Model Validation Report: BTC Option Models on Deribit

Independent validation · Author: **Meet Babariya** · Generated automatically 16 Oct 2026, 15:56 UTC · Code and data: github.com/MeetBabariya/options-validation-lab

1. Executive summary

Seven models were validated for marking and hedging BTC options: SVI, SSVI, SABR, Heston, Bates, Black-Scholes and an adaptive challenger delta. **SVI and SABR are fit for marking**: they price 98% and 86% of quotes inside the bid-ask spread. **Heston is not approved**: it needs implausible dynamics, misprices short-dated options and hedges worse than Black-Scholes. For hedging, **no fixed smile-dynamics assumption beats the plain sticky-strike delta** over a year, because the spot-volatility correlation changes sign between months (-0.36 to +0.60).

0.17	23/23	18,555	-15.1%
SVI median IV error, vol pts	implementation tests passing	out-of-sample option-days hedged	Heston hedge vs Black-Scholes

Model	Intended use	Decision	Evidence	Conditions
SVI (per expiry)	Marking and interpolating the daily smile	Approved with conditions	Median IV error 0.17 vol pts, 98% of quotes inside bid-ask, 0 butterfly and 0 calendar violations on the latest surface.	Run the arbitrage checks on every fit; do not use the fitted smile as a model of smile dynamics (sticky-moneyness delta loses 12% vs BS).
SSVI (global)	Arbitrage-free benchmark and extrapolation	Approved with conditions	Arbitrage-free by construction; median IV error 1.04 vol pts.	Not for marking short-dated options: one skew parameter misses the short-dated put skew.
SABR, beta = 1 (per expiry)	Marking; delta with Bartlett correction	Approved for marking; hedge not approved	Median IV error 0.38 vol pts. Bartlett delta -2.8% vs BS (-15.3 to +15.6%).	Bartlett delta wins only when spot-vol correlation is negative; do not use as the default hedge.
Heston (global)	Pricing and hedging across expiries	Not approved	Median IV error 1.45 vol pts with implausible parameters (kappa at the 200 bound on 15% of days); delta -15.1% vs BS (-27.8 to -6.7%).	Do not use; jumps (Bates) improve the fit but not the dynamics, see F8.

Model	Intended use	Decision	Evidence	Conditions
Bates (Heston + jumps)	Pricing and hedging across expiries	Not approved	Median IV error 0.60 vol pts (Heston 1.45). Fits by pricing a rare crash (0.08 per year, mean jump -22%) while kappa stays near 180; delta -15.0% vs BS (-26.5 to -6.7%).	Use only as a cross-maturity pricing benchmark; jump parameters are identified only as a combination (F8).
Black-Scholes, sticky strike	Default delta hedge	Approved	Benchmark that no fixed smile-dynamics delta beats over the year.	Keep as the production delta; monitor challengers.
Adaptive spot-vol delta (30 days)	Challenger hedge	Monitor	+8.5% vs BS (-0.7 to +15.4%); beats BS on only 46% of days.	Track for another 6 months; promote only if the interval excludes zero.

2. Scope and intended use

The models are assessed for two uses: **marking** (producing an implied-volatility surface consistent with the market and free of static arbitrage) and **hedging** (producing a delta that minimises the one-day hedging error). Out of scope: exotic pricing, vega hedging, transaction costs and capital.

3. Data

Dataset	Source	Size	Use
Live option chains	Deribit public API (no key), snapshot daily at 08:00 UTC	latest: 878 options, 11 expiries	Fit, arbitrage, identifiability
Historical chain states	Rebuilt from Deribit trade history: marks, trade IV, index	365 daily windows (07:00 to 09:00 UTC)	Hedging backtest, parameter history
Hedging pairs	Same option observed on consecutive days	24,329 pairs, 18,555 in the out-of-sample test	Outcome analysis

Cleaning. Only out-of-the-money options with a two-sided market and |delta| of at least 5% are used; deep-wing quotes are mostly tick rounding. **Forward.** Deribit prices options in coin on the forward of each expiry. The historical forward is recovered from each trade's price and Deribit's IV (one equation, unique root). Checked against live forwards, the error is below 0.5 bp of the forward.

4. Conceptual soundness

Model	Key assumption	Known weakness
SVI	Smile per expiry; Lee moment bound; Durrleman butterfly condition checked	Static: says nothing about how the smile moves
SSVI	Global surface, arbitrage-free under Gatheral-Jacquier conditions	One skew parameter for all maturities

Model	Key assumption	Known weakness
SABR (beta = 1)	Lognormal forward with stochastic vol per expiry	Hagan expansion; per-expiry parameters
Heston	Mean-reverting stochastic variance, no jumps	Cannot produce steep short-dated smiles without jumps
Bates	Heston plus lognormal jumps (Merton)	Eight parameters; jump size, frequency and dispersion trade off
BS sticky strike	Each option keeps its own IV when spot moves	Ignores spot-vol co-movement

5. Implementation verification

23 of 23 automated tests pass in this run. Key checks against independent references:

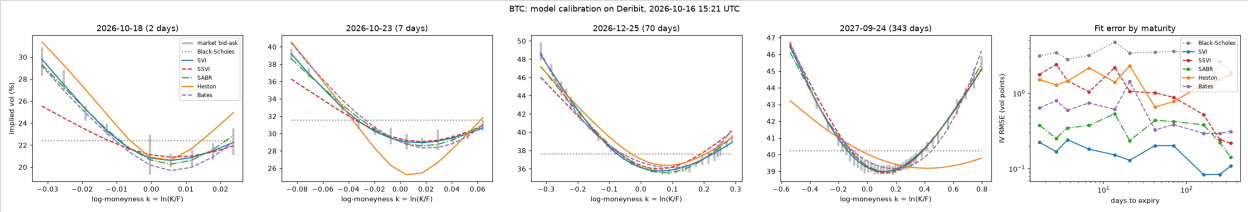

Check	Result
Heston COS price vs published Fang & Oosterlee (2008) value 5.785155450	**pass**
Heston COS vs independent numerical integration (2 to 365 days)	**pass**
Heston reduces to Black-Scholes when vol of vol is zero	**pass**
Calibration recovers known Heston parameters (synthetic data)	**pass**
Calibration recovers known SABR parameters (synthetic data)	**pass**
Bates with constant variance matches an independent Merton jump-diffusion series	**pass**
Bates without jumps equals Heston; characteristic function is a martingale	**pass**
Calibration recovers known Bates parameters (synthetic data)	**pass**
Durrleman check flags the known arbitrage slice (Gatheral & Jacquier 2014)	**pass**
Sticky-moneyness delta equals total derivative	**pass**
Bartlett delta equals derivative with alpha following the forward	**pass**
Forward inference round-trip on Deribit coin prices	**pass**
Min-variance regression recovers known coefficients	**pass**

6. Outcome analysis: fit to the market

Latest snapshot BTC_20261016T1521Z.csv.gz: 283 usable quotes from 2 to 343 days. SVI shows 0 butterfly and 0 calendar arbitrage violations.

Model	Median IV error (vol pts)	Quotes inside bid-ask
Black-Scholes	3.36	11%
SVI	0.17	98%

Model	Median IV error (vol pts)	Quotes inside bid-ask
SSVI	1.04	60%
SABR	0.38	86%
Heston	1.45	25%
Bates	0.60	56%

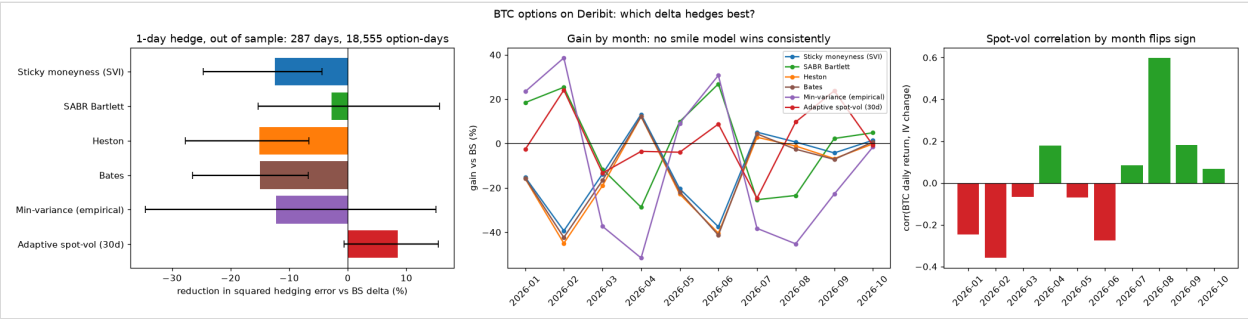

Market bid-ask (grey) against each model for four expiries, and fit error by maturity.

7. Outcome analysis: hedging

One-day delta hedges for every out-of-the-money option observed on consecutive days. Gain = 1 - SSE(model) / SSE(BS). Empirical deltas are fitted only on earlier months. Intervals: bootstrap over whole days.

Delta	Gain vs BS	95% interval	Gain, vega-scaled	Days beating BS
BS (sticky strike)	benchmark			
Sticky moneyness (SVI)	-12.4%	-24.7 to -4.4%	-8.5%	45%
SABR Bartlett	-2.8%	-15.3 to +15.6%	-2.0%	55%
Heston	-15.1%	-27.8 to -6.7%	-10.2%	42%
Bates	-15.0%	-26.5 to -6.7%	-10.4%	43%
Min-variance (empirical)	-12.2%	-34.6 to +15.1%	-5.9%	44%
Adaptive spot-vol (30d)	+8.5%	-0.7 to +15.4%	+5.2%	46%

Gains with intervals, gains by month, and spot-vol correlation by month.

8. Stability and identifiability

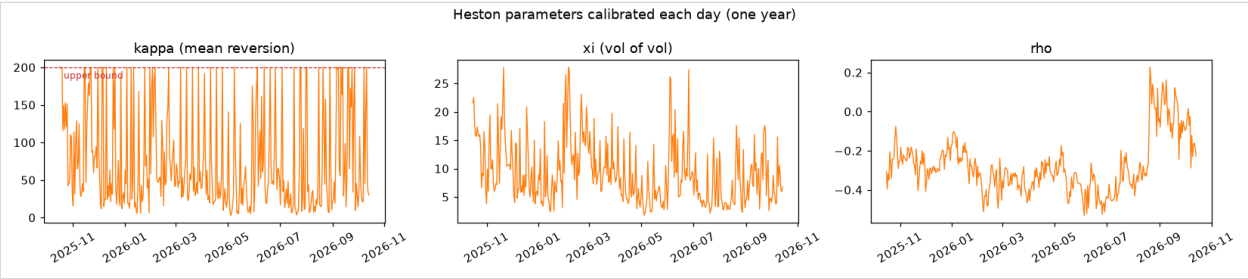

Within a day: quotes redrawn uniformly inside their bid-ask spreads and Heston refitted 20 times. Parameters move by at most 1.3%: the data pins them down, so the misfit is not estimation noise.

Heston parameter	Mean	Std	Coefficient of variation
v0	0.044	0.000	1.1%
kappa	61.384	0.808	1.3%
theta	0.172	0.000	0.1%
xi	9.806	0.128	1.3%
rho	-0.211	0.002	0.8%

Bates, 10 refits: the jump parameters move more and are almost perfectly correlated with each other (|correlation| 0.93); the combined jump variance is far more stable than its parts.

Bates parameter	Mean	Std	Coefficient of variation
v0	0.009	0.002	18.0%
kappa	180.089	4.818	2.7%
theta	0.122	0.000	0.3%
xi	7.540	0.183	2.4%
rho	-0.255	0.007	2.9%
lam	0.080	0.002	2.3%
muj	-0.772	0.023	3.0%
sj	1.020	0.017	1.6%
jump variance per year	0.131	0.003	2.4%

Across days: over the backtest year, Heston's kappa reached its upper bound on 15% of days.

9. Findings register

ID	Severity	Area	Finding	Recommendation
F1	High	Heston	Fitting BTC smiles requires implausible dynamics (median kappa 47, vol of vol 8.0) and still misprices short-dated options; parameters are tightly identified (bootstrap CV 1% or less), so this is model misspecification, not noise.	Do not use. A jump extension (Bates) was tested, see F8.
F2	High	Smile-dynamics deltas	Spot-vol correlation changes sign between months (-0.36 to +0.60). Every fixed assumption wins in one regime and loses in the other.	Keep sticky-strike as default; evaluate regime-adaptive deltas.
F3	Medium	Sticky moneyness, Heston	Both imply that IV rises when BTC rises; over the year it fell. Hedging error is 12% and 15% worse than BS, intervals exclude zero.	Do not use sticky-moneyness deltas for BTC.
F4	Medium	All hedges	Hedging errors are heavy-tailed: the worst 1% of option-days carry about 45% of the squared error.	Report robust metrics alongside SSE; stress-test on large-move days.
F5	Medium	SSVI	One global skew parameter cannot match the short-dated BTC put skew (1 to 2 vol pts).	Use per-expiry SVI or SABR for short maturities.
F6	Low	SVI implementation	Very short expiries produced degenerate fits (negative total variance, extreme deltas) until optimiser starts were scaled to the slice and total variance was bounded at zero. Fixed and covered by tests.	Keep the regression tests; alert on any |delta| > 1.
F8	High	Bates	Adding jumps cuts the median IV error from 1.45 to 0.60 vol pts, but only by pricing a rare, very large crash (0.08 per year, mean jump -22%). The jump parameters trade off along a ridge (|correlation| 0.93 in the bootstrap); only combinations such as the jump variance (0.131 per year, CV 2%) are pinned down. The diffusion stays implausible (kappa 180). The objective has a second, much worse basin with frequent small jumps, and over the year the daily fit switches between the two: jump rate below 0.5 per year on 42% of days, at the 60 bound on 21%. Hedge: -15.0% vs BS (-26.5 to -6.7%), no better than Heston.	Not for hedging. Calibrate from several starts in both basins; report jump risk as a combination, not separate parameters.
F7	Low	Data	Backtest uses Deribit marks, not executable quotes, with daily rebalancing and no costs; only options trading on both days are included.	Repeat with order-book snapshots when available.

10. Limitations

Marks are Deribit model prices, not executable quotes. Hedging is daily with no transaction costs. Option and forward are measured at each instrument's last trade in the window, and only options that trade on both days are included, which favours liquid strikes. Results cover BTC only.
